Formal Verification of Systems Software

Material and slides created by

Jon Howell and Manos Kapritsos

New Dafny syntax: modules

Modules allow us to break up our code into multiple parts/namespaces

```
module Host {
      predicate Next() { ... }
}

module DistributedSystem {
      import Host
      predicate Next() { Host.Next() }
}
```

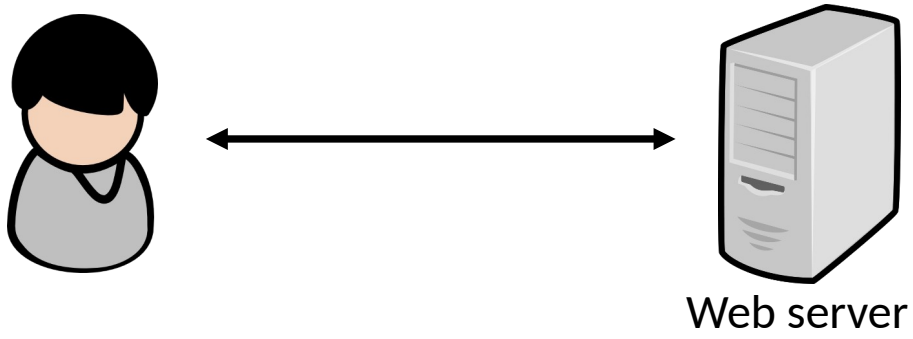
Introduction to distributed systems

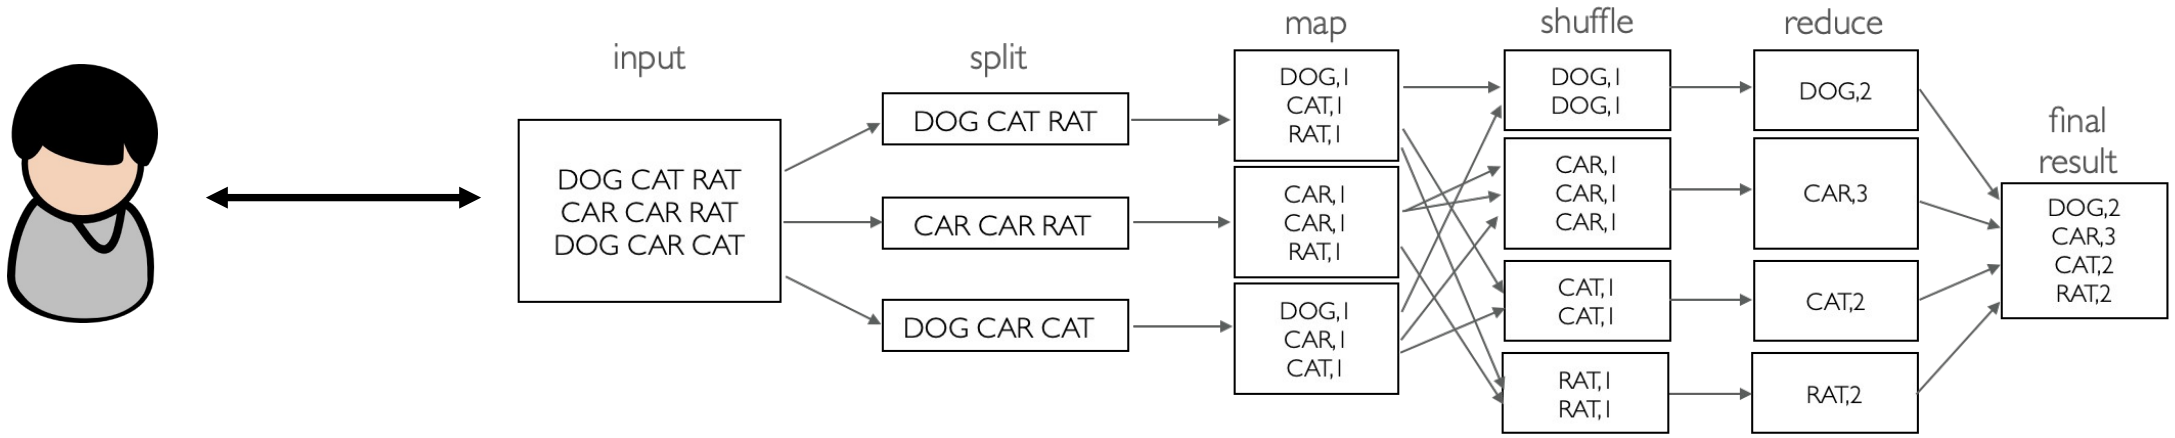
What is a distributed system?

A collection of distinct processes that:

- are spatially separated
- communicate with one another by exchanging messages
- have non-negligible communication delay
- do not share fate
- have separate, imperfect, unsynchronized physical clocks

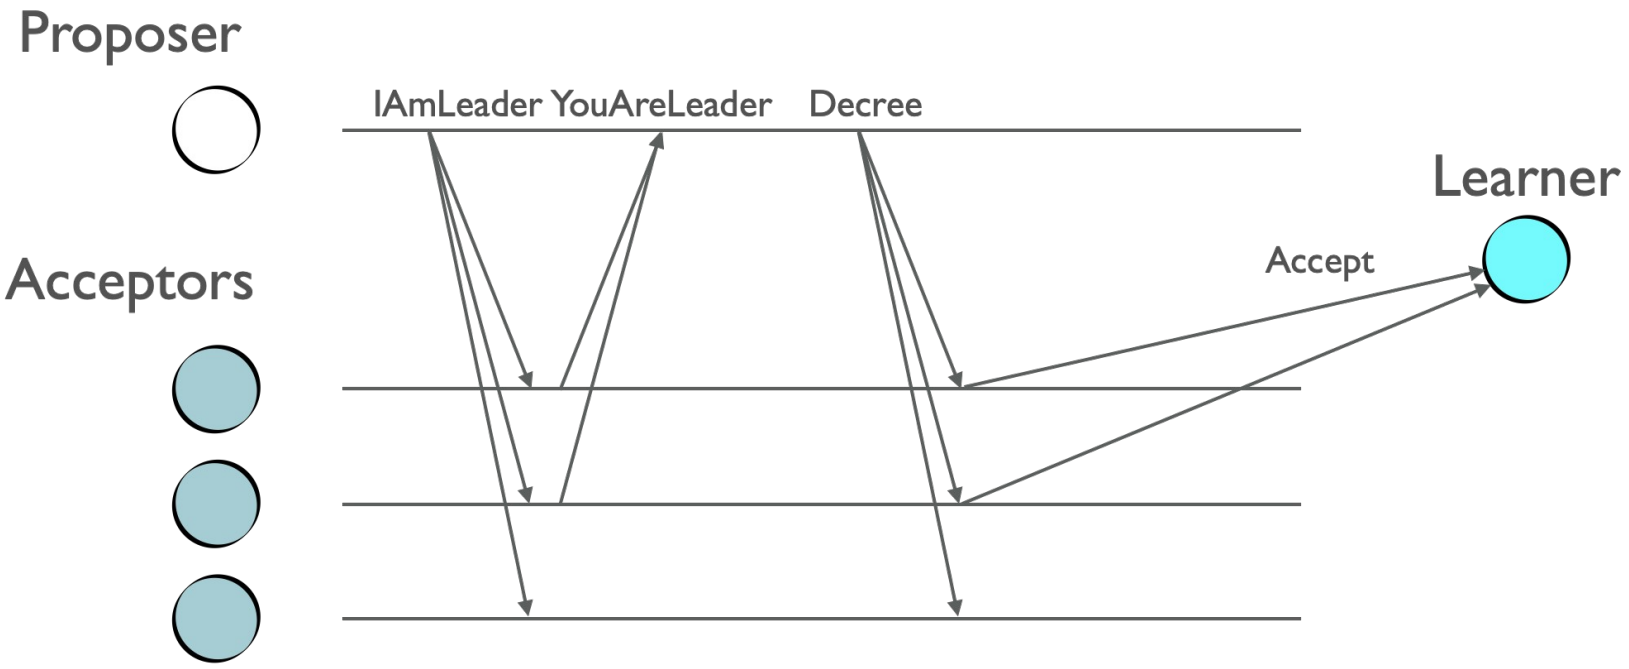
Other examples of distributed systems





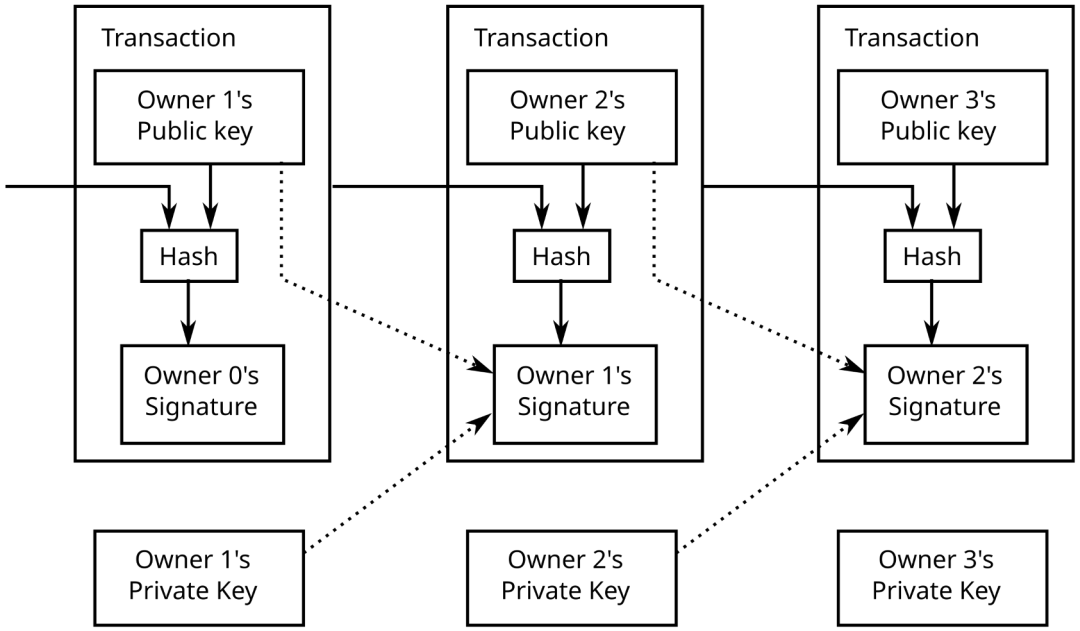
Other examples of distributed systems

The Paxos protocol

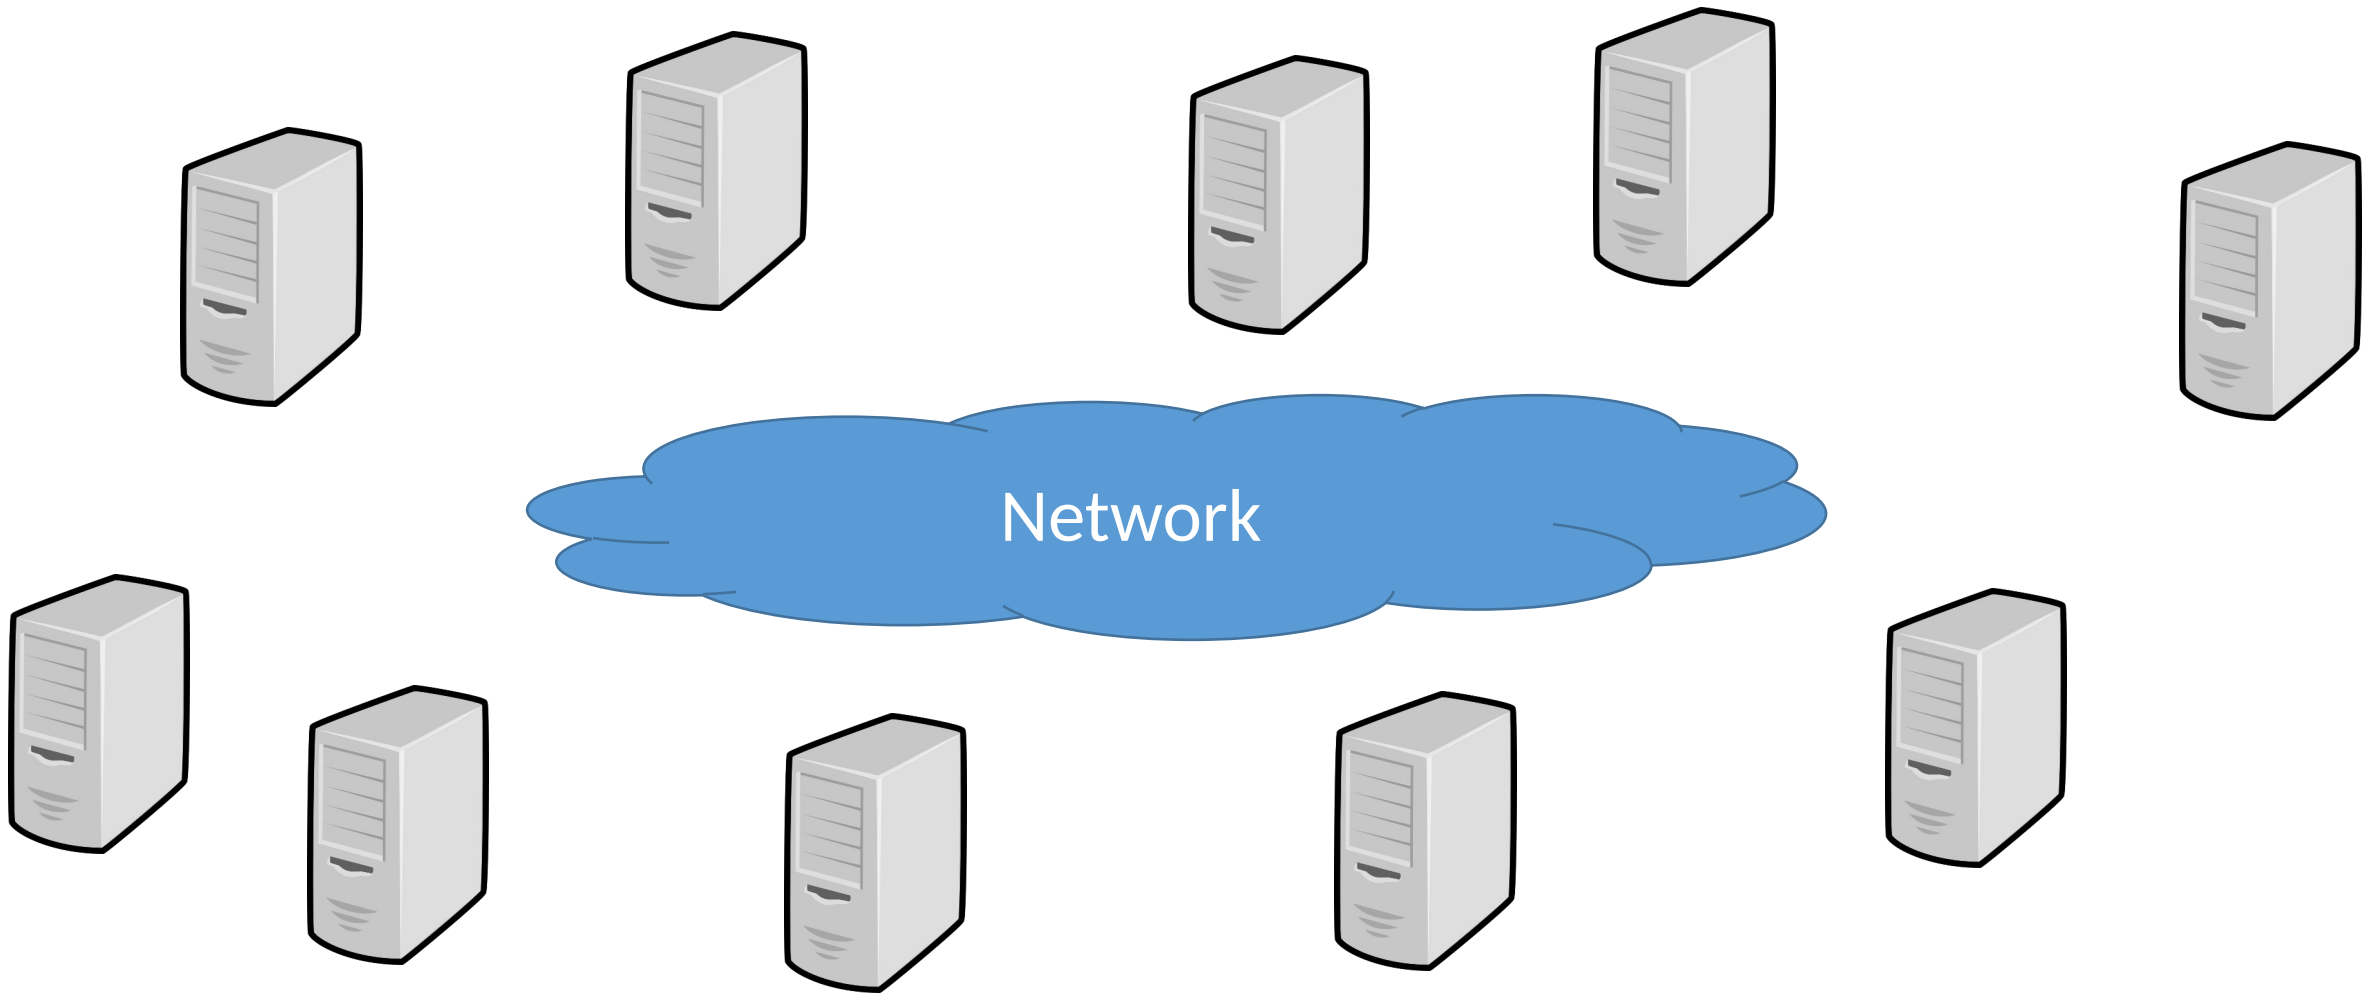


Other examples of distributed systems

The Bitcoin blockchain



A distributed system



Atomic Commit (Problem Set 3)

-Do you take each other?

-I do.

-I do.

-I now pronounce you atomically committed.

Atomic Commit: the objective

Preserve data consistency for distributed transactions

Example: book a hotel and flight on Expedia

Atomic Commit: the setup

- One coordinator
- A set of participants
  - Allowed to be empty in our model
- Every participant has an "input" value, called vote/preference

$$vote_i \in \{Yes, No\}$$

- Every participant/coordinator has an "output" value, called decision

$$decision_i \in \{Commit, Abort\}$$

- We are ignoring the possibility of failures

Atomic Commit: the spec (simplified to ignore failures)

- AC-1: All processes that reach a decision reach the same one
- AC-3: The Commit decision can only be reached if all processes vote Yes
- AC-4: If ~~there are no failures and~~ all processes vote Yes, then the decision must be Commit

AC-2 and AC-5 ignored

Two Phase Commit (2PC)

Coordinator c

Participant p_i

1. sends VOTE-REQ message to all participants

2. sends $vote_i$ to coordinator
   if $vote_i$ == No
   then $decision_i$:= Abort

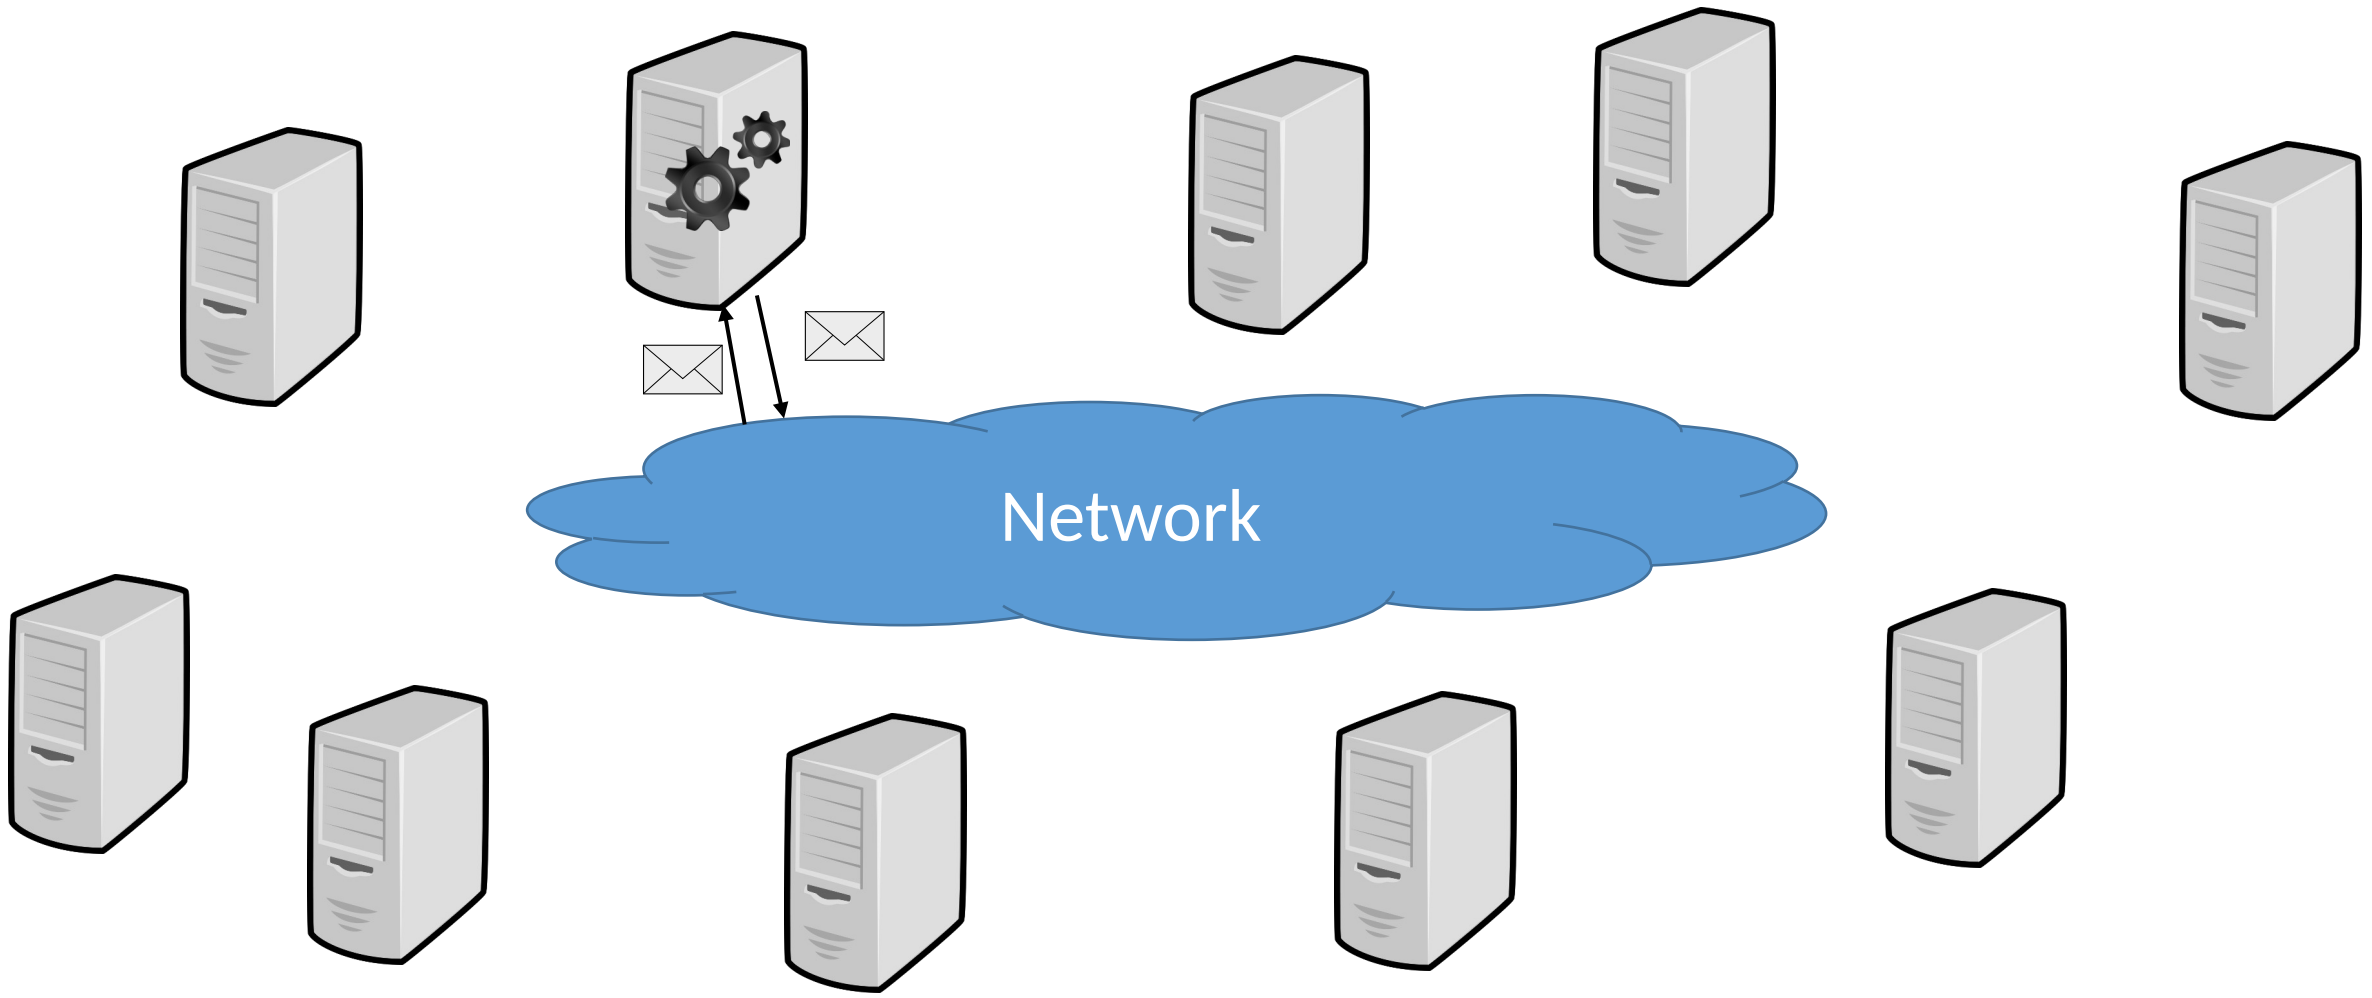
3. Wait for all votes to come in
   If all votes are Yes then
      $decision_c$:= Commit
      Send Commit message to all
   else
      $decision_c$:= Abort
      Send Abort message to all who voted Yes

4. If received Commit then
      $decision_i$:= Commit
   else
      $decision_i$:= Abort

Administrivia

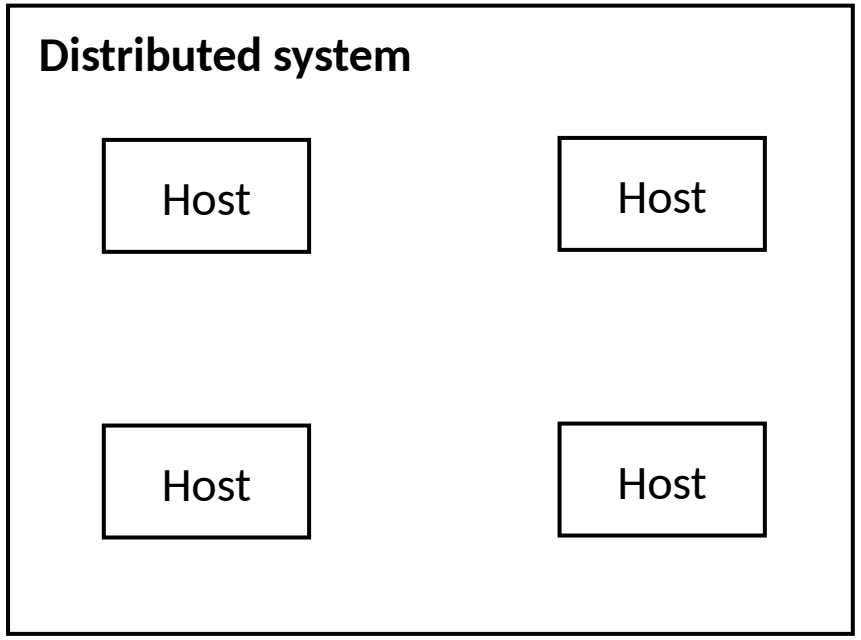
- Problem set 3 (Chapter 5) has been released and is due Oct 24
- Start looking for partners for Project 1 (released after PS3)
- Midterm evaluations are up
  - **Please provide feedback!** (Currently 2 out of 28)
  - Note the additional questions
- Midterm exam on October 17
  - Time: 6-8pm
  - Location: BBB1670
  - Will contact you for time/location if you have accommodations
- We will release practice exams tonight

A distributed system



Modeling distributed systems

A distributed system is composed of multiple hosts



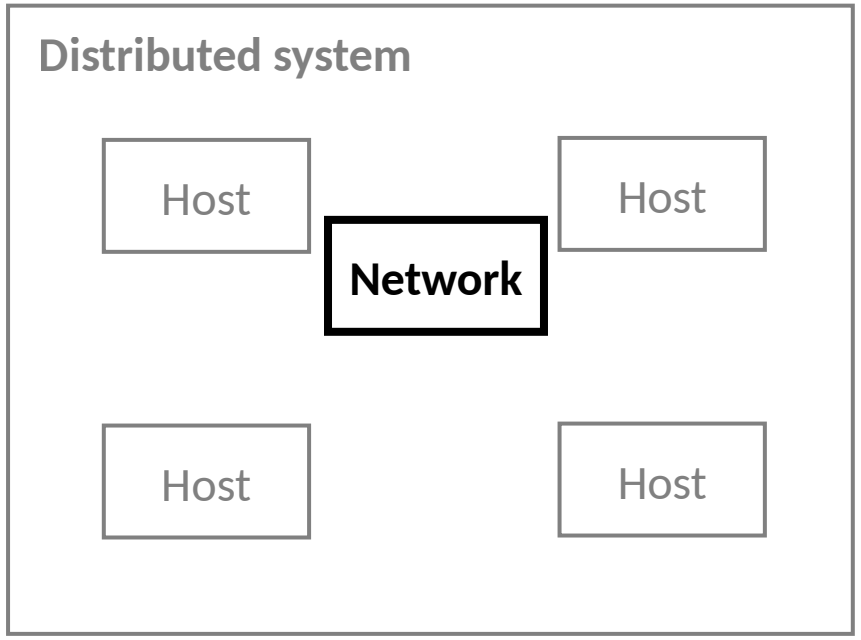
Distributed System: attempt #1

```
module DistributedSystem {
  datatype Variables =
    Variables(hosts:seq<Host.Variables>)

  predicate Next (v:Variables, v’:Variables, hostid: nat)
{
    && Host.Next(v.hosts[hostid],v'.hosts[hostid]))
    && forall otherHost:nat | otherHost != hostid ::
        v’.hosts[otherHost] == v.hosts[otherHost]
  }
}
```

Defining the network

```
datatype Option<T> = Some(value:T) | None
datatype MessageOps = MessageOps(
                    recv:Option<Message>,
send:Option<Message>)
```

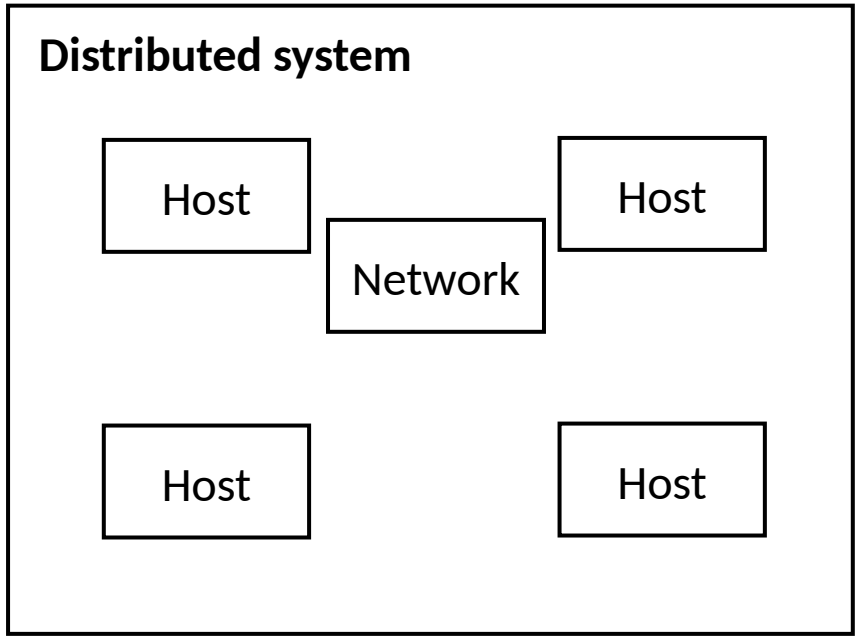


Network module

```
module Network {
  datatype Variables =
    Variables(sentMsgs: set<Message>)

  predicate Next(v, v', msgOps:MessageOps) {
    // can only receive messages that have been sent
    && (msgOps.recv.Some? ==> msgOps.recv.value in
v.sentMsgs)
    // Record the sent message, if there was one
    && v'.sentMsgs ==
       v.sentMsgs + if msgOps.send.None? then {}
                    else {msgOps.send.value}
  }
}
```

A distributed system is composed of multiple hosts **and a network**



Distributed system: attempt #2

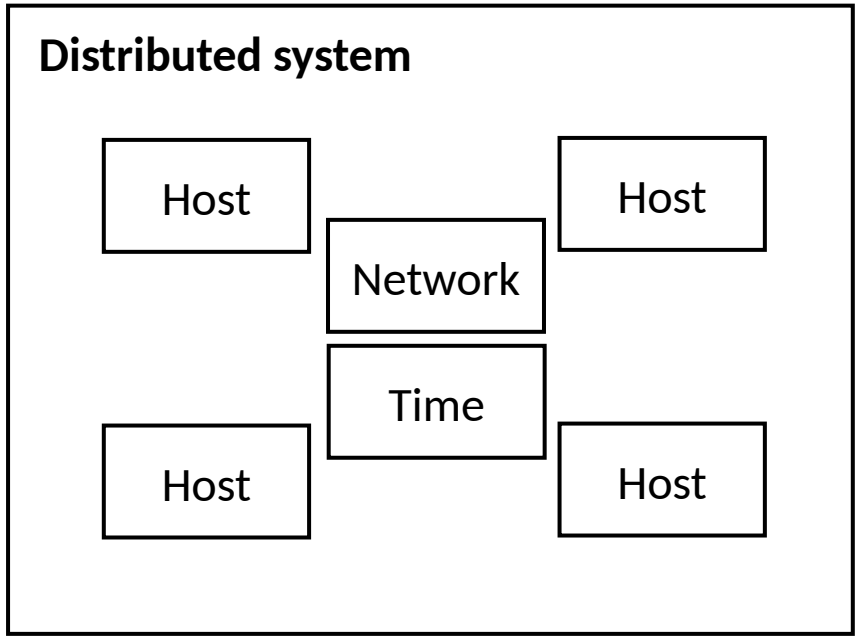
```
module DistributedSystem {
  datatype Variables =
    Variables(hosts:seq<Host.Variables>,
              network: Network.Variables)

  predicate HostAction(v, v', hostid, msgOps) {
    && Host.Next(v.hosts[hostid],v'.hosts[hostid],msgOps))
    && forall otherHost:nat | otherHost != hostid ::
        v'.hosts[otherHost] == v.hosts[otherHost]
  }

  predicate Next(v, v', hostid, msgOps: MessageOps) {
    && HostAction(v, v', hostid, msgOps)
    && Network.Next(v, v', msgOps)
  }
}
```

Binding variable

A distributed system is composed of multiple hosts, **a network and clocks**

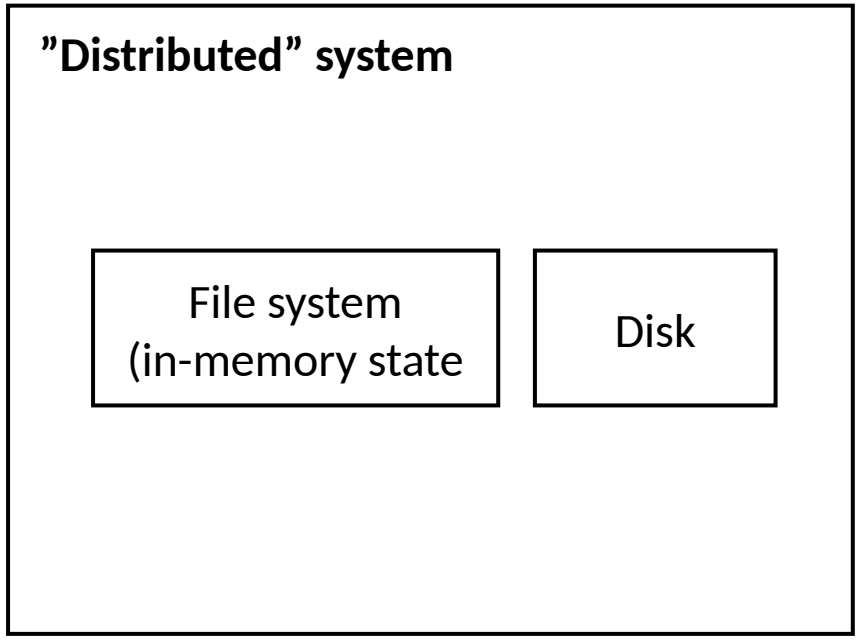


Distributed system: attempt #3

```
module DistributedSystem {
  datatype Variables =
    Variables(hosts:seq<Host.Variables>,
              network: Network.Variables,
              time: Time.Variables)

  predicate Next(v, v', hostid, msgOps: MessageOps,
clk:Time) {
    || (&& HostAction(v, v', hostid, msgOps)
        && Network.Next(v, v', msgOps)
        && Time.Read(v.time, clk))
    || (&& Time.Advance(v.time, v'.time)
        && v'.hosts == v.hosts
        && v'.network == v.network)
  }
}
```

This modeling applies to all asynchronous systems

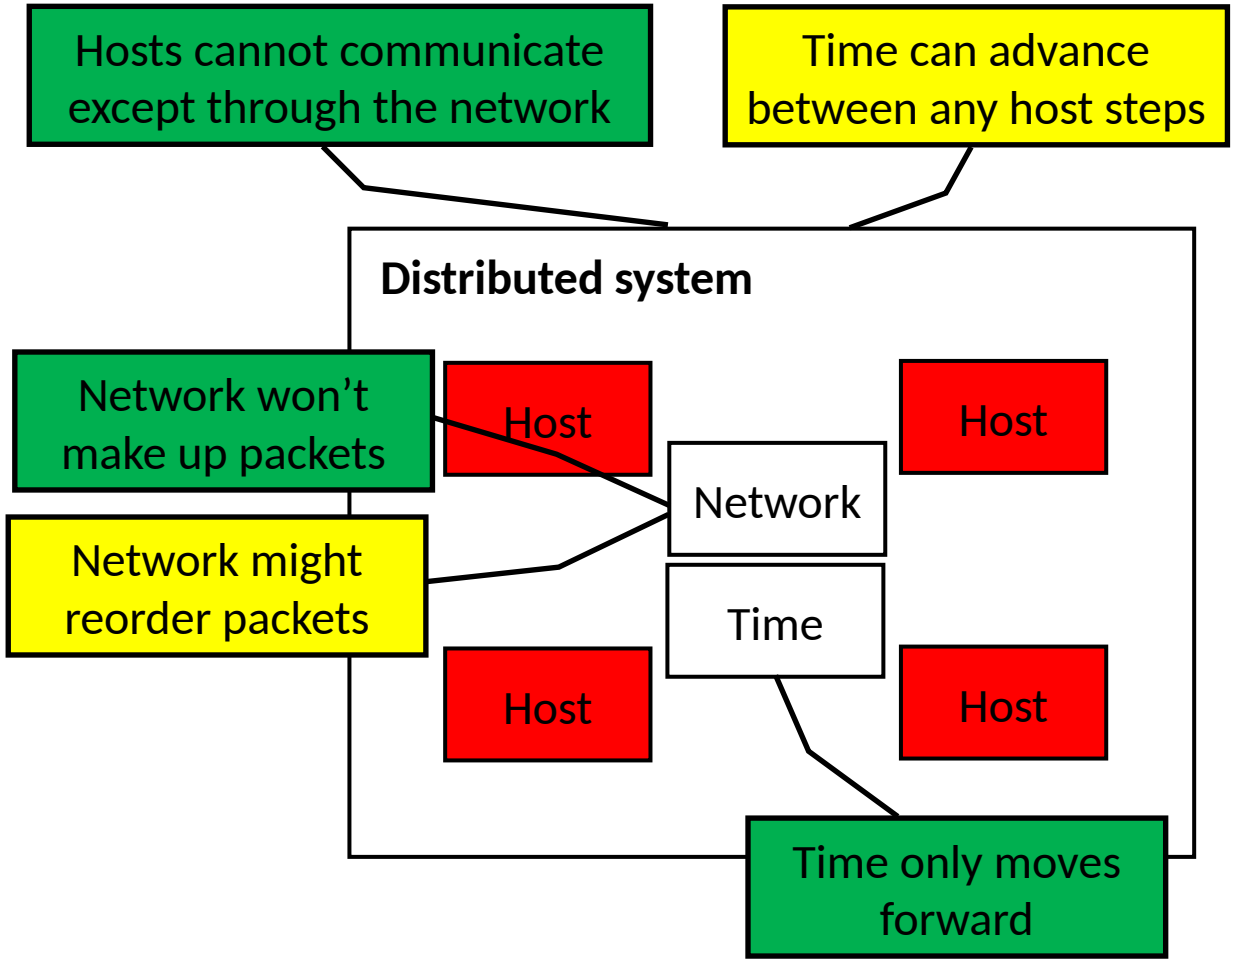


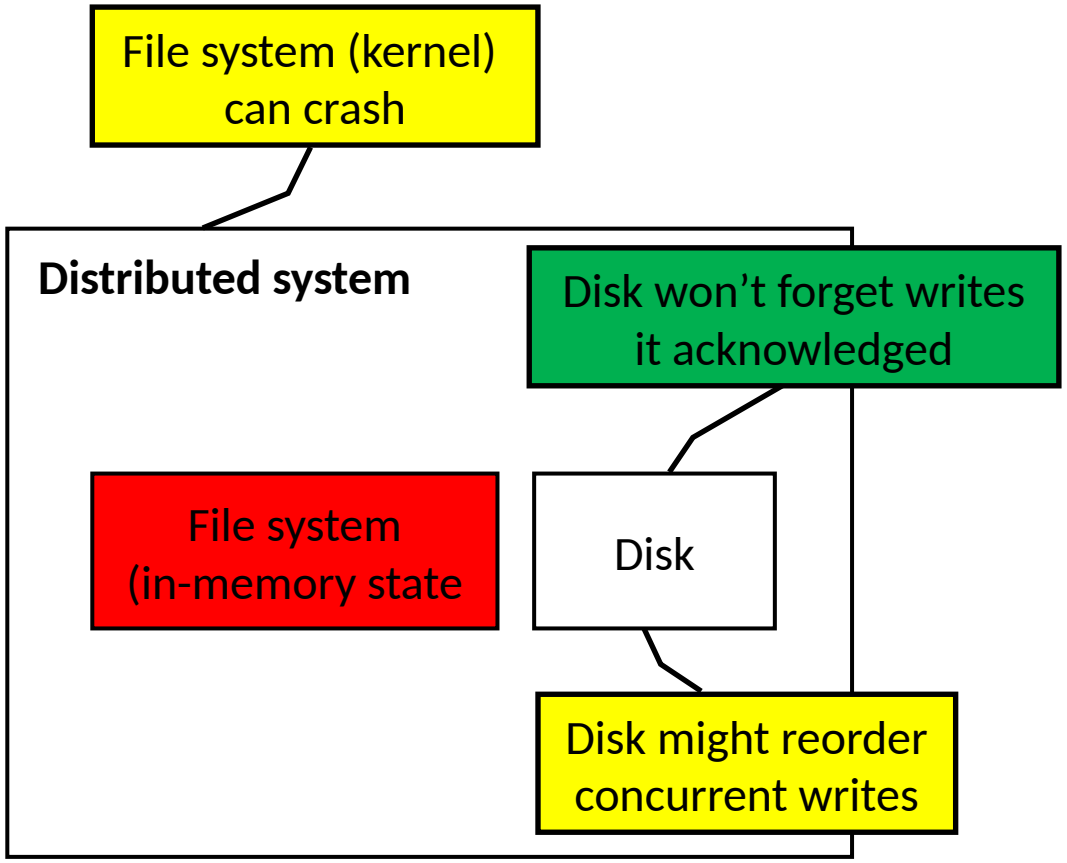
```
module DistributedSystem {
  datatype Variables =
    Variables(fs: FileSystem.Variables,
              disk: Disk.Variables)

  predicate Next(v, v') {
    || (exists io ::
        && FileSystem.Next(v.fs, v'.fs, io)
        && Disk.Next(v.disk, v'.disk, io)
    || ( // Crash!
        && FileSystem.Init(v'.fs)
        && v'.disk == v.disk
       )
  }
}
```

Binding variable

Trusted vs proven





SPECIFICATION sandwich: the systems specification
